## LAMPIRAN

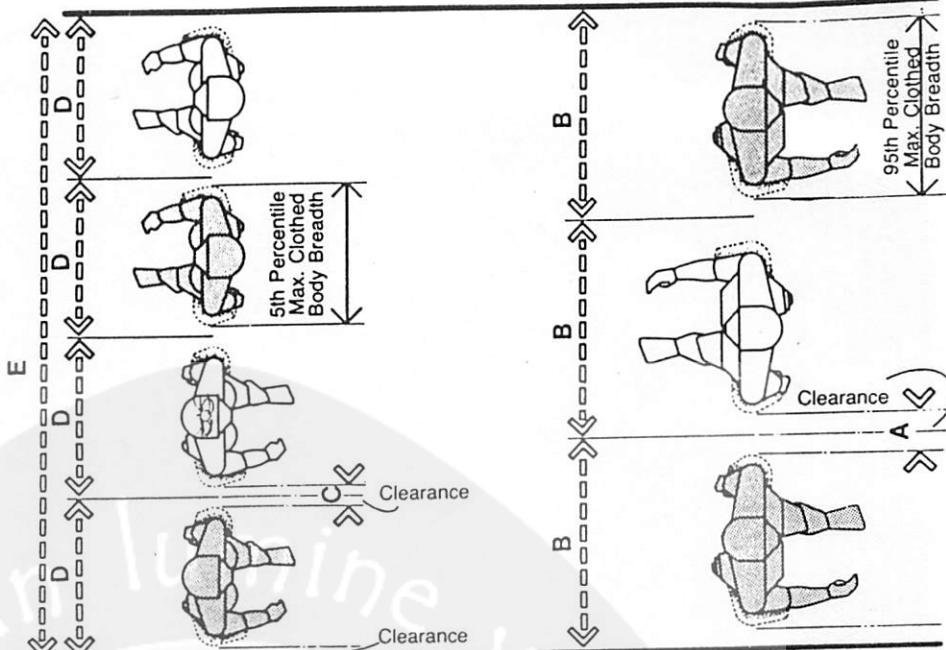

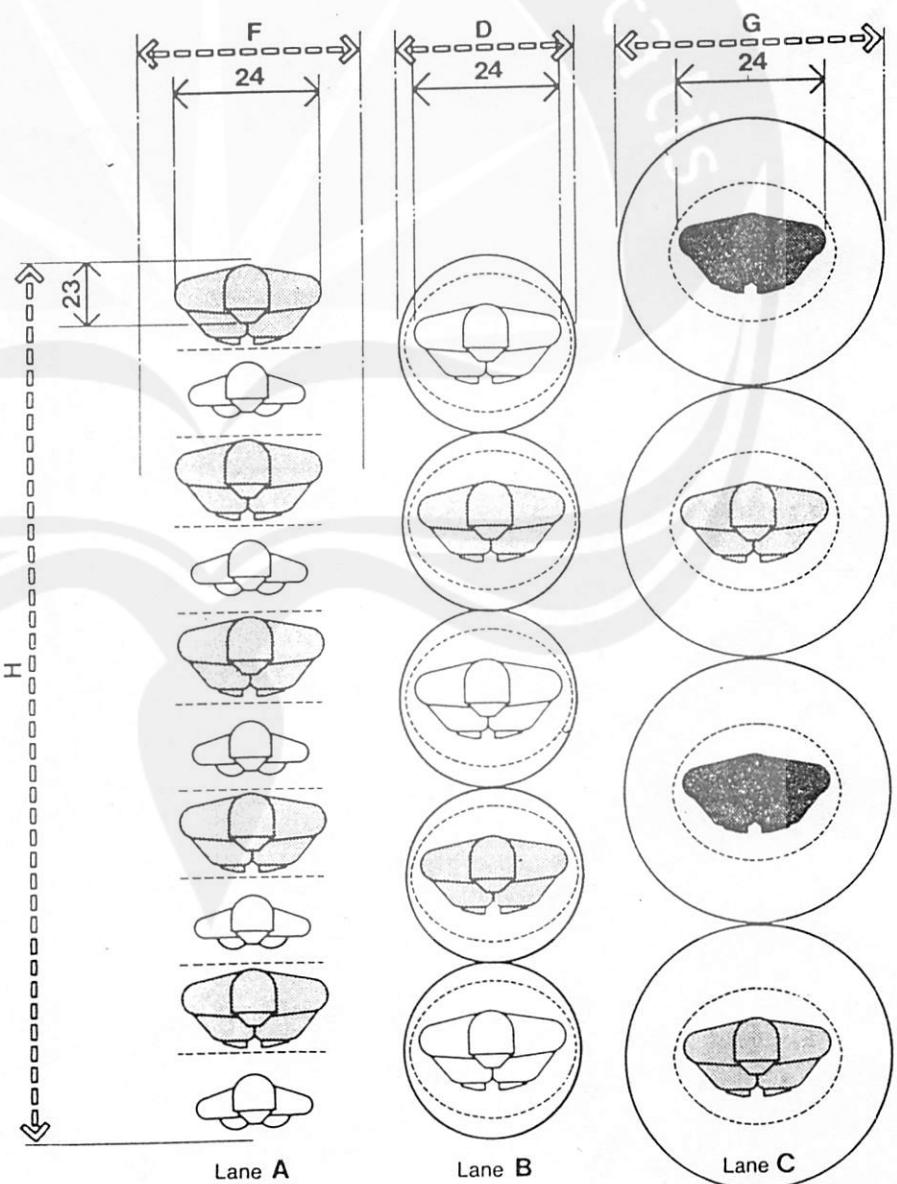

## 8.1 HORIZONTAL CIRCULATION SPACES

The purpose of the drawing at the top is to provide some idea of the physical relationship between human dimension and corridor width in terms of the number of lanes that can be accommodated. The row with three persons abreast is based on 95th percentile maximum clothed body breadth, while the row with four abreast is based on 5th percentile data. The corridor width was arbitrarily selected as 96 in, or 243.8 cm. The drawing should not be taken literally. The statistical likelihood of having the lineup of body sizes shown, at any single point in time, would be remote unless the space was originally intended to serve a specific user population of larger or smaller body size. Moreover, the 24-in, or 61-cm, lane with a 1.6-in clearance is obviously not intended as a standard.

The bottom drawing is intended to provide some insight into relative densities possible within a 120-in, or 308.4-cm, queue. Lane A shows as many people lined up as possible, with no regard for comfort or body contact. When an allowance for clothing is added to the maximum body breadth, the people in lane A would be pressed tightly together, violating all notions of personal space and comfort. Lanes B and C show the number of people that could be lined up, based on the densities of 3 and 7 sq ft, or .28 and .65 sq m per person, respectively.

ACCOMMODATION OF SMALL AND LARGE USERS ABREAST IN A 96-IN (243.8-CM) CORRIDOR OR PASSAGE WIDTH

QUEUE LINES / COMPARATIVE DENSITIES

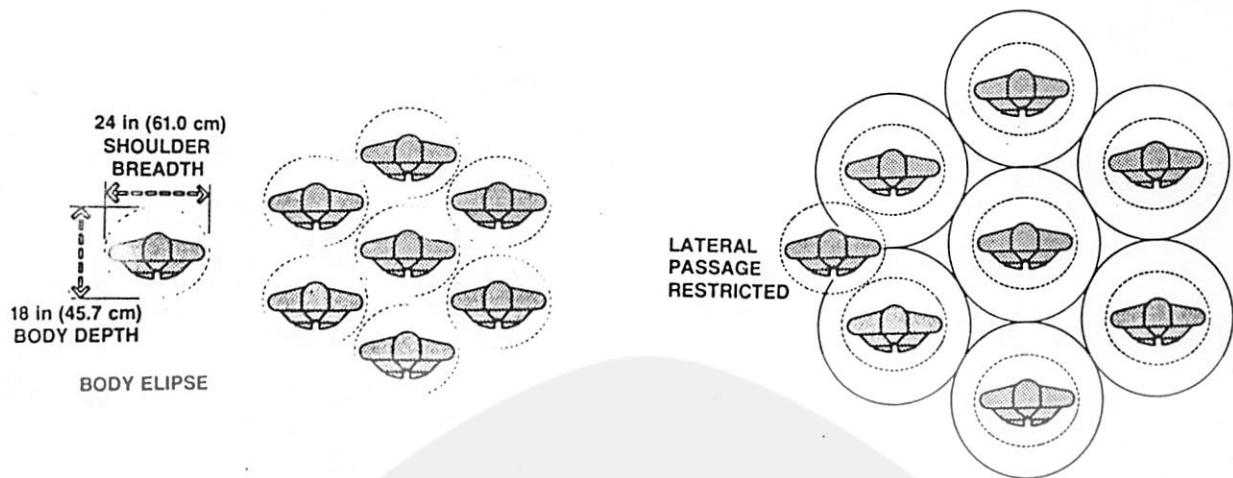

Figure 2-4 (left). Illustration of Fruin's "touch zone" based on a "body ellipse" buffer zone with a minor axis related to body depth and a major axis related to shoulder breadth, allowing a queuing area of 3 sq ft, or 0.29 sq m, per person. Below this boundary the frequency of body contact between pedestrians is increased. Figures 2-4 to 2-7 adapted from Fruin, *Pedestrian Planning and Design*, 1971. Figure 2-5 (right). Illustration of Fruin's "no touch zone," based on an expanded interperson spacing of 36 in, or 91.4 cm, and a 7 sq ft, or 0.65 sq m, area per person. Fruin contends that body contact can be avoided between 3 and 7 sq ft, or 0.29 to 0.65 sq m, per person.

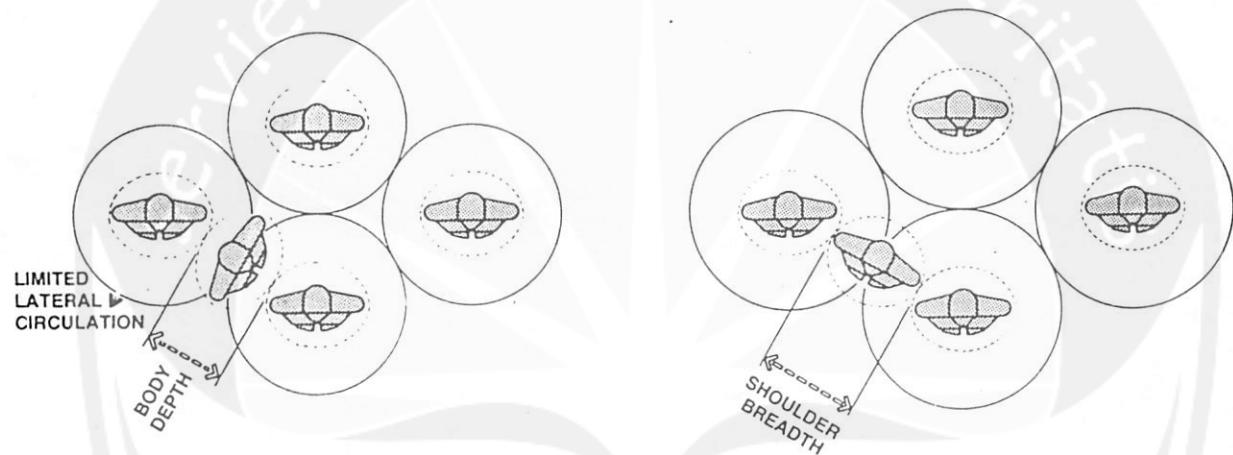

Figure 2-6 (left). Illustration of Fruin's "personal comfort zone," expanding the body buffer zone to a 42-in, or 106.7-cm, diameter and a 10-sq ft, or 0.93-sq m, area. A full body depth separates standees, allowing for limited lateral circulation by moving sideways. Figure 2-7 (right). Illustration of Fruin's "circulation zone," expanding the body buffer zone to a 48-in or 121.9-cm, diameter and 13-sq ft, or 1.21-sq m, area. Fruin contends that 10 to 13 sq ft, or 0.93 to 1.21 sq m, per person would allow circulation without disturbing others.

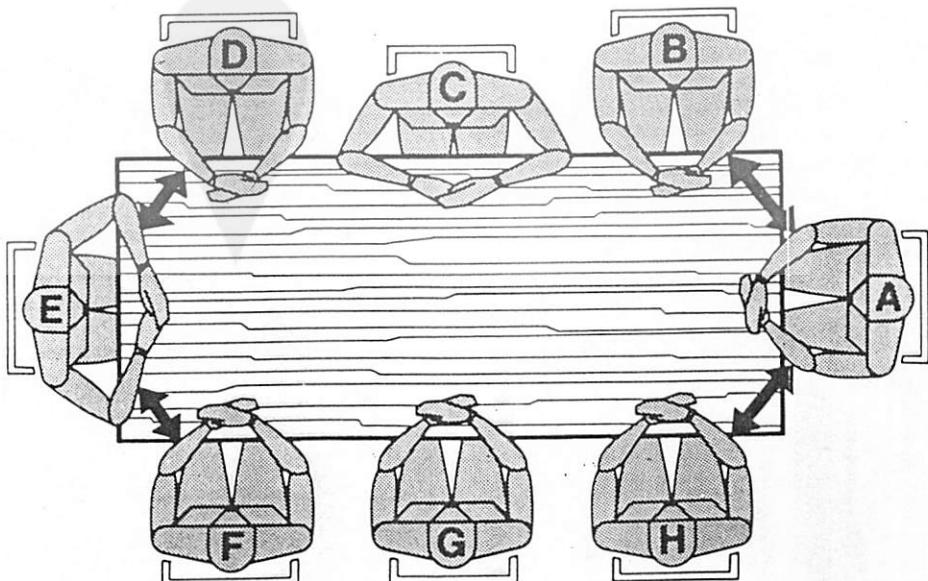

Figure 2-8. Sommer's experiment at the Saskatchewan Hospital involved a seating arrangement as shown at right. It was observed that greater interaction between people occurred across the corners AB, EF, and ED. Adapted from *Sociometry*.
