

BAB V

KESIMPULAN DAN SARAN

5.1. Kesimpulan

Berdasarkan hasil komparatif studi desain kolom antara SK SNI T-15-1991-03 (DPU, 1991) dengan ACI 318-1995 (PCA, 1996) yang telah dilakukan, dapat ditarik kesimpulan sebagai berikut :

1. Penghitungan yang dilakukan antara SK SNI T-15-1991-03 (DPU, 1991) dengan ACI 318-1995 (PCA, 1996) memiliki perbedaan yang disebabkan oleh faktor reduksi ϕ sebesar 0,65 untuk sengkang ikat biasa dan 0,7 untuk sengkang spiral pada peraturan SK SNI T-15-1991-03 (DPU, 1991), sedangkan pada peraturan ACI 318-1995 (PCA, 1996) ϕ sebesar 0,7 untuk sengkang ikat biasa dan 0,75 untuk sengkang spiral. Faktor pembebanan yang digunakan dalam SK SNI T-15-1991-03 (DPU, 1991) adalah $1,2DL + 1,6 LL$ dan $1,4DL + 1,7LL$ untuk ACI 318-1995 (PCA, 1996), serta rumus - rumus yang digunakan.
2. Program kolom beton bertulang dibuat dengan bahasa pemrograman Borland Delphi 6, yang berbasis windows. Program kolom beton bertulang ini digunakan untuk mendisain dan menganalisa kolom dengan beban aksial yang diinginkan, dan menghitung momen uniaksial dan biaksial yang dibebankan pada kolom tersebut. Program ini berdasarkan pada peraturan SK SNI T-15-1991-03 (DPU, 1991). Program tersebut berhasil dibuat dengan selisih penghitungan maksimal sebesar 0,6 % dari hitungan manual.

3. Perbedaan hasil terbesar penghitungan yang dilakukan antara program GEAR (ACECOMS, 2001) dengan manual adalah kuat tarik maksimum sebesar 29,65 % , dan momen ultimit sebesar 37,696 %. Hal ini terjadi karena perbedaan faktor pembeban, faktor reduksi, asumsi penghitungan kolom bulat yang diequivalkan ke kolom persegi, dan rumus – rumus yang dipergunakan dengan persyaratan ACI 318-1995 (PCA, 1996). Selain dari itu penggunaan rumus pendekatan Whitney juga tidak konservatif untuk kolom yang mengalami keruntuhan tekan mendekati daerah seimbang. Hal ini disebabkan rumus whitney berdasarkan persamaan garis lurus.
4. Perbedaan konversi yang dilakukan dengan penghitungan kolom yang memakai peraturan SK SNI T-15-1991-03 (DPU, 1991) dengan ACI 318-1995 (PCA, 1996). Faktor konversi ini dapat dipergunakan untuk mengkonversikan hasil hitungan dari SK SNI T-15-1991-03 (DPU, 1991) ke peraturan ACI 318-1995 (PCA, 1996). Faktor konversi yang dihitung untuk beban aksial dan momen ultimit yang berbeda yang disebabkan oleh faktor pembebanan antara lain :
 - a. Faktor konversi untuk kolom berpenampang persegi :
 - Luas tulangan terpakai (P_u) = 126,93 %
 - b. Faktor konversi untuk kolom berpenampang lingkaran :
 - Luas tulangan terpakai (P_u) = 126,69 %

5.2. Saran

Sebagai penutup dari penulisan tugas akhir ini penyusun hendak menyampaikan sedikit saran yang mungkin bermanfaat bagi penulisan tugas akhir yang serupa. Saran-saran yang dapat penyusun berikan adalah sebagai berikut ini.

1. Metoda penghitungan dapat dilanjutkan dengan metoda eksak yang hasil penghitungannya lebih konservatif.
2. Untuk penggunaan program sebaiknya diperhatikan diagram iteraksi dengan pembebanan dan besar momen yang mendekati daerah seimbang. Beban dan momen yang mendekati daerah seimbang adalah kolom yang ideal bagi penggunaan strukturnya.
3. Penggunaan bahasa pemrograman yang lebih baik dapat mempermudah dalam pembuatan program karena fasilitas yang disediakan berbeda antara satu bahasa pemrograman dengan bahas pemrograman yang lain.

Berdasarkan SK SNI T-15-1991-03

Project Information:

Project = Tugas Akhir

Title = Validasi

Client = Atma Jaya Yogyakarta

Organization = Wek'e Dewe

Engineer = Kuntadi

Design Criteria

Design Code = ACI-318-95, Design Method = USD

Concrete Stress Block = ACI-Whitney Rectangular

Design Procedure

The program performs the calculations in accordance with the ACI-318-95 Code for Structural Concrete

Procedure for Cross-section Design

1. Compute the resultant applied moment as $M_{uxy} = \text{Sqr}(M_{ux}^2 + M_{uy}^2)$.
2. Select a trial reinforcement ratio, starting with minimum ratio of 1%, and distributing rebars along the perimeter.
3. Compute the maximum axial capacity in compression, P_{no} and tension P_{nt} , and check against applied loads.
4. Locate the neutral axis angle and its depth to satisfy applied load P_u and the resultant moment M_{uxy} . This is done by trial and error procedure. The internal stress resultants for each angle and depth of neutral axis angle are computed (see procedure below) and then compared with applied loads. This process is repeated until close agreement is found.
5. If capacity in step 3 or 4 is found to be not enough, then reinforcement is increased until maximum allowable ratio (8%) is reached.
6. Cross-section is declared as inadequate if it requires more than maximum allowable steel ratio

Procedure for Computing Stress-Resultants

1. The stress resultants are computed by using the first principles approach.
2. Strain in concrete and steel is determined depending upon the direction and depth of neutral axis.
3. Concrete force is computed by integrating the stress field (rectangular or parabolic stress curve) over the cross-section using the Green's Theorem.
4. Steel stress is computed by summation of force in each bar, corresponding to stress at that location.
5. The computed stress resultants are reduced by appropriate capacity reduction factors for the Ultimate Strength Design (or Working Strength Design) method.
